

## Revision

$$y'' + p(x)y' + q(x)y = F(x) \quad \text{--- } \# \text{ Inhomogeneous}$$

$$y'' + p(x)y' + q(x)y = 0 \quad \text{--- } * \text{ homogeneous}$$

Th① Linear combination of  $n$  solutions of  $*$  is also a solution to  $*$ .

Th② If  $y_1$  and  $y_2$  are two solutions to  $*$  on  $[a, b]$ . Then  $w(y_1, y_2)$  is either identically zero on  $[a, b]$  or never zero on  $[a, b]$ .

Moreover  $w$  is zero on  $[a, b] \Leftrightarrow y_1$  and  $y_2$  are LD on  $[a, b]$ .

Th③ Existence and uniqueness theorem for  $\#$  and  $*$ .

Ex.  $y''' + 2y'' + 4xy' + x^2y = 0$

$y(2) = 0$	has only trivial solution on $\mathbb{R}$ .
$y'(2) = 0$	
$y''(2) = 0$	

Def: Set of 2 LI solutions of  $*$  is called fundamental set of solutions to  $*$

Th④ If  $y_1$  and  $y_2$  are two LI solutions to  $*$  then general sol. to  $*$  is:  $y = c_1y_1 + c_2y_2$

Generalization: Fundamental set of solutions to  $n^{th}$ -order linear homogeneous equation has  $n$  LI solutions. And general solution is their linear combination.

Remember Thm(A) and Thm(B) for  $*$

SL Ross (3<sup>rd</sup> Edition)

↳ many of them, you can solve orally.

• How to find general sol. of 2<sup>nd</sup> order homogeneous constant coefficient linear ODEs

(\*)  $y'' + py' + qy = 0$ ; p and q are constants

Guess:  $y = e^{mx}$  is a solution of (\*) for some m

Verify: put  $y = e^{mx}$  in (\*) and obtain

$$m^2 e^{mx} + pm e^{mx} + q e^{mx} = 0$$

$$\Rightarrow (m^2 + pm + q) e^{mx} = 0$$

Thus  $e^{mx}$  is a solution of (\*)  $\Leftrightarrow m^2 + pm + q = 0$

$$m = \frac{-p \pm \sqrt{p^2 - 4q}}{2}$$

Thus question is to find roots of this equation.

If  $m_1$  and  $m_2$  are two roots of AE, then there are three possibilities :-

case 1  $m_1 \neq m_2$  and both are real

case 2  $m_1$  and  $m_2$  are complex

$$m_1 = \alpha + i\beta \text{ and } m_2 = \alpha - i\beta$$

case 3  $m_1 = m_2$  and both are real

This equation is called auxiliary equation of (\*) (AE)

$$\begin{aligned} y'' + py' + qy &= 0 \\ &\equiv D^2 y + pDy + qy = 0 \\ &\equiv (D^2 + pD + q)y = 0 \\ &\equiv Ly = 0 \end{aligned}$$

where  $L \equiv D^2 + pD + q$

{ replace  
D by m

$$m^2 + pm + q$$

Case 1  $(P^2 - 4Q > 0)$

Let  $m = m_1, m_2$  be two roots of AE,  $m_1 \neq m_2$  and real.

Then  $y_1 = e^{m_1 x}$

$$y_2 = e^{m_2 x}$$

are two LI solutions to  $\circledast$

Case 2  $\rightarrow P^2 - 4Q < 0$

Let  $m_1, m_2 = a \pm bi$

Then  $y_1 = e^{(a+bi)x}$  are two complex  
 $y_2 = e^{(a-bi)x}$  solution.

But we want real solution.

Invoke Thm A

If  $y = e^{(a+bi)x}$

$$= e^{ax} e^{ibx}$$

$$= e^{ax} (\cos bx + i \sin bx)$$

is a complex solution. Then

$$y_1 = e^{ax} \cos bx$$

$$y_2 = e^{ax} \sin bx$$

are two LI real solutions to  $\circledast$

Case 3

$$b^2 - 4q = 0 \text{ then roots are } m_1 = m_2 = -\frac{b}{2}$$

If  $m_1, m_2$  are two real and equal roots of AE, i.e.

$$m_1 = m_2 = m \text{ (say)} = -\frac{b}{2}$$

then  $y_1 = e^{mx}$  is a solution to  $\textcircled{*}$

To find another LI solution, invoke them  $\textcircled{B}$

If  $y_1$  is a solution of  $\textcircled{*}$   
 then  $y_2 = y_1 \cdot u$  is also a solution  
 where  $u = \int \frac{1}{y_1^2} e^{-\int p dx} dx$

$$\begin{aligned} \text{Here } u &= \int \frac{1}{e^{2mx}} e^{-px} dx \\ &= \int \frac{e^{-px}}{e^{2mx}} dx \quad (\because m = -\frac{b}{2}) \end{aligned}$$

$$= x$$

Thus

$$y_1 = e^{mx}$$

$$y_2 = x e^{mx}$$

are two LI solutions to  $\textcircled{*}$

## Relook

$$y'' + py' + qy = 0 \quad (p, q \text{ are constants})$$

Auxiliary Eqn (AE) :  $m^2 + pm + q = 0$

Find its roots (say,  $m_1, m_2$ )

Distinct real roots	Conjugate complex roots	Repeated real roots
$m_1 \neq m_2$ (real)	$m_1 = a+ib$ $m_2 = a-ib$	$m_1 = m_2 = m$ real
$y_1 = e^{m_1 x}$ $y_2 = e^{m_2 x}$	$y_1 = e^{ax} \cos bx$ $y_2 = e^{ax} \sin bx$	$y_1 = e^{mx}$ $y_2 = xe^{mx}$
$y = c_1 e^{m_1 x} + c_2 e^{m_2 x}$	$y = e^{ax} (c_1 \cos bx + c_2 \sin bx)$	$y = e^{mx} (c_1 + c_2 x)$

## Examples

### ODE

$$y'' - 3y' + 2y = 0$$

AE

$$m^2 - 3m + 2 = 0$$

$$\Rightarrow (m-1)(m-2) = 0$$

roots of AE

$$m = 1, 2$$

General solution

$$y = c_1 e^x + c_2 e^{2x}$$

$$y'' - 6y' + 25y = 0$$

$$m^2 - 6m + 25 = 0$$

$$\Rightarrow m = \frac{6 \pm \sqrt{36-100}}{2}$$

$$m = 3 \pm 4i$$

$$y = e^{3x} [c_1 \cos 4x + c_2 \sin 4x]$$

$$y'' - 6y' + 9y = 0$$

$$m^2 - 6m + 9 = 0$$

$$\Rightarrow (m-3)^2 = 0$$

$$m = c_1 e^{3x} + c_2 x e^{3x}$$

$$= e^{3x} [c_1 + c_2 x]$$

Imp Observation  $y \equiv 0$  is always a solution of homogeneity equation. And any other solution tends to 0 as  $x \rightarrow \infty$  when real roots (and real part of complex roots) are negative.

Similarly, we can solve higher order constant coefficient linear homogeneous ODEs.

Case 1 ( $n$  distinct real roots):  $m_1, m_2, \dots, m_n$   
then  $e^{m_1 x}, e^{m_2 x}, \dots, e^{m_n x}$  are  $n$  LI solutions.

Case 2 If  $a \pm bi$  are  $k$ -fold roots of the auxiliary equation, then corresponding part of general solution may be written as

$$e^{ax} \left[ (C_1 + C_2 x + C_3 x^2 + \dots + C_k x^{k-1}) \cos bx + (C_{k+1} + C_{k+2} x + C_{k+3} x^2 + \dots + C_{2k} x^{k-1}) \sin bx \right]$$

Case 3 If root  $m$  occur  $k$  times then corresponding part of general solution may be written as

$$(C_1 + C_2 x + \dots + C_k x^{k-1}) e^{mx}$$

The algorithm can be extended to higher order ODEs

Example:

①  $y^{(4)} - 5y'' + 4y = 0$

$$(D^4 - 5D^2 + 4)y = 0$$

AE  $m^4 - 5m^2 + 4 = 0$

$$\Rightarrow m = -1, 1, -2, 2$$

Then general soln:  $y = c_1 e^{-x} + c_2 e^x + c_3 e^{-2x} + c_4 e^{2x}$

②  $y^{(4)} - 8y'' + 16y = 0$

AE  $m^4 - 8m^2 + 16 = 0$

$$\Rightarrow m = -2, -2, 2, 2$$

Gen. Soln.:  $y = e^{-2x}(c_1 + c_2 x) + e^{2x}(c_3 + c_4 x)$

③  $y^{(4)} - 2y^{(3)} + 2y'' - 2y' + y = 0$

AE  $m^4 - 2m^3 + 2m^2 - 2m + 1 = 0$

$$\Rightarrow m = 1, 1, \pm i$$

Gen. Soln.:  $y = e^x(c_1 + c_2 x) + (c_3 c_4 x + c_4 \sin x)$

④ If roots of a 4<sup>th</sup> order homogeneous constant coefficient ODE are

$$2+3i, 2+3i, 2-3i, 2-3i$$

Then  $y = e^{2x}[(c_1 + c_2 x) c_3 e^{3x} + (c_3 + c_4 x) \sin 3x]$

Note: for 2<sup>nd</sup> order, if roots are  $2 \pm 3i$ , then  $y = e^{2x}[c_1 c_3 e^{3x} + c_2 \sin 3x]$

④ If roots of 6<sup>th</sup> order homogeneous constant coefficient ODE are

$$1, 1, \boxed{i, i, -i, -i}$$

Then Gen Sol.  $\therefore y = e^x (c_1 + c_2 x) + (c_3 + c_4 x) \cos 2x + (c_5 + c_6 x) \sin 2x$

⑤ If roots of the AE corresponding to a certain 10<sup>th</sup> order homogeneous linear constant coefficient ODE are

$$4, 4, 4, 4, \underline{2+3i}, \underline{2-3i}, \underline{2+3i}, \underline{2-3i}, 2+3i, 2-3i$$

Then

$$y = e^{4x} (c_1 + c_2 x + c_3 x^2 + c_4 x^3) + e^{2x} [(c_5 + c_6 x + c_7 x^2) \cos 3x + (c_8 + c_9 x + c_{10} x^2) \sin 3x].$$

All problems from 43-46.

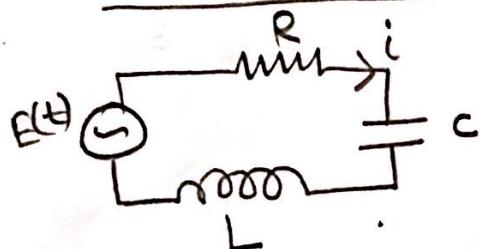

### Example

- ① spring-mass-damper system under some external force

see similarity

- ② LRC Circuit

ODE

$L q'' + R q' + \frac{1}{C} q = E(t)$

By Kirchhoff's Law

$$L \frac{di}{dt} + R i + \frac{1}{C} q = E(t)$$

put  $i = \frac{dq}{dt}$  and obtain

OR

{ differentiate wrt + }

$L i'' + R i' + \frac{1}{C} i = \frac{dE}{dt}$

$L \frac{d^2q}{dt^2} + R \frac{dq}{dt} + \frac{1}{C} q = E$

$q(0) = q_0$

$\frac{dq}{dt}(0) = i(0) = i_0$

## Spring-mass-damper ODE

$$my'' + cy' + ky = E(t)$$

Initial data  
 $y(0) = y_0$  (initial displacement)  
 $y'(0) = 0$  (no initial velocity)

### Case 1

free undamped motion i.e.  $\begin{cases} E \equiv 0 \\ c = 0 \end{cases}$

$$my'' + ky = 0$$

$$\Rightarrow y'' + \frac{k}{m}y = 0 \equiv y'' + \omega_0^2 y = 0$$

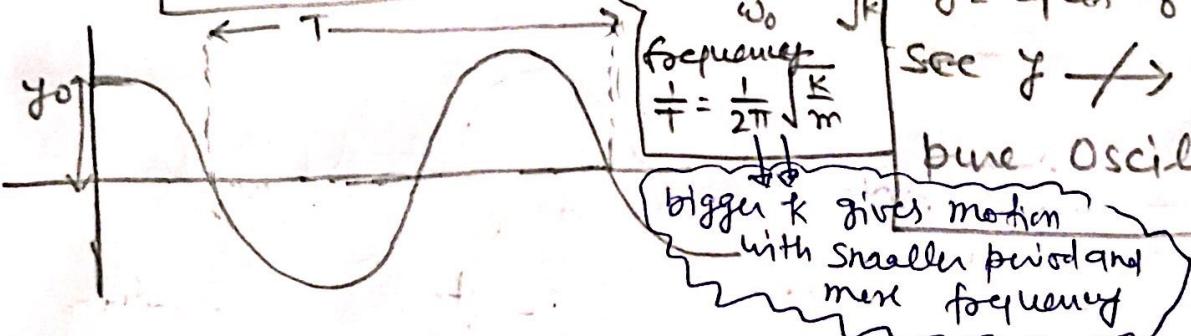

Notation  
 $\omega_0^2 = \frac{k}{m}$

If initial data is

$$y(0) = y_0; y'(0) = 0$$

then

$$y = y_0 \cos \omega_0 t$$

Its solution

$$AE \div m^2 + \omega_0^2 = 0$$

$$\Rightarrow m = \pm \omega_0 i$$

$$y = C_1 \cos \omega_0 t + C_2 \sin \omega_0 t$$

see  $y \rightarrow 0$  as  $t \rightarrow \infty$

pure oscillation cont.

bigger k gives motion with smaller period and more frequency

### Case 2 free damped motion

i.e.  $E \equiv 0$

$$my'' + cy' + ky = 0$$

$$\Rightarrow y'' + 2b y' + \omega_0^2 y = 0 \quad \left[ \text{Notation } 2b = \frac{c}{m}, \omega_0^2 = \frac{k}{m} \right]$$

Solution: AE:  $m^2 + 2b m + \omega_0^2 = 0$

$$\Rightarrow m = \frac{-2b \pm \sqrt{4b^2 - 4\omega_0^2}}{2} = -b \pm \sqrt{b^2 - \omega_0^2}$$

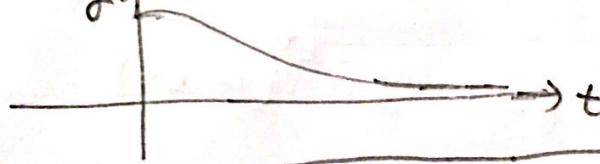

Subcase 1 ( $b > \omega_0$ ) (overdamped case)  
 Then we obtain two distinct real roots and both are -ive. Hence  $y \rightarrow 0$  as  $t \rightarrow \infty$

Assume: roots are  $m_1, m_2$  ( $m_1, m_2 < 0$  and  $m_1 \neq m_2$ )

$$\text{Then } y = C_1 e^{m_1 t} + C_2 e^{m_2 t}$$

$$\begin{aligned} C_1 + C_2 &= y_0 \\ m_1 C_1 + m_2 C_2 &= 0 \end{aligned} \Rightarrow \begin{aligned} C_1 &= -\frac{m_2 y_0}{m_1 - m_2} \\ C_2 &= \frac{m_1 y_0}{(m_1 - m_2)} \end{aligned}$$

$$y = -\frac{m_2 y_0}{m_1 - m_2} e^{m_1 t} + \frac{m_1 y_0}{m_1 - m_2} e^{m_2 t}$$

If I/c
$y(0) = y_0$
$y'(0) = 0$

(Overdamping)  
 No Oscillations.

Subcase 2 ( $b < \omega_0$ ) i.e.  $b^2 < \omega_0^2$  ( $\because b > 0$ ) [Underdamped case]

Then we obtain two complex roots (in pair) such that real part is  $-b$  (i.e. a negative number)

$$m = -b \pm \alpha i \quad \alpha = \sqrt{\omega_0^2 - b^2}$$

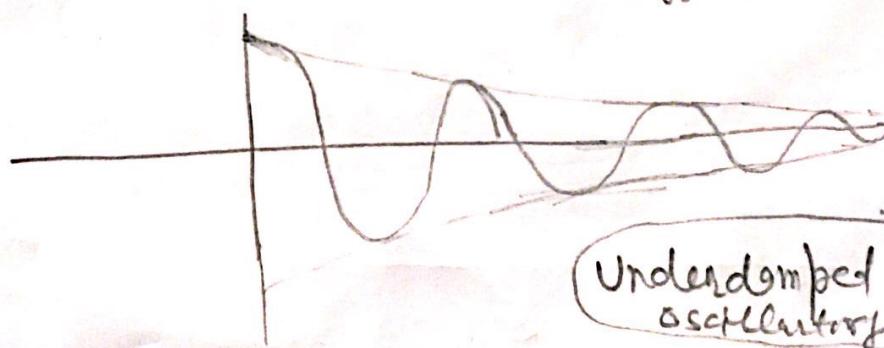

$$\text{then } y = e^{-bt} [C_1 \cos \alpha t + C_2 \sin \alpha t]$$

$$\begin{aligned} y(0) &= y_0 \\ y'(0) &= 0 \end{aligned} \Rightarrow$$

$$C_1 = y_0; \quad C_2 = 0$$

$$y = e^{-bt} C_1 \cos \alpha t$$

amplitude is  $y e^{\alpha t}$ . It decreases as  $t$  increases and  $y \rightarrow 0$  as  $t \rightarrow \infty$ .

Underdamped oscillatory Motion

Subcase 3 (critical damping case) ( $b = \omega_0$ )

then it is a case of two real and equal roots.

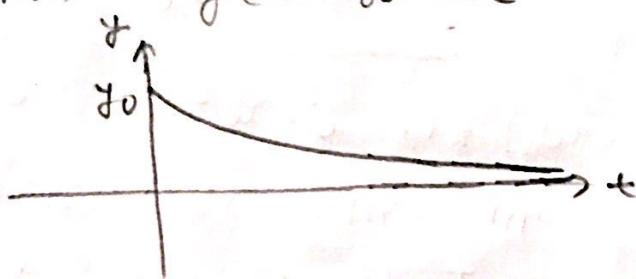

$m = -b, -b$ . Then solution is

$$y(t) = e^{-bt} (c_1 + c_2 t) \rightarrow 0 \text{ as } t \rightarrow \infty$$

further there is no oscillations and damping is just enough to prevent any oscillation.

If  $y(0) = y_0$  and  $y'(0) = 0$ , then we obtain  $c_1 = y_0$  and  $c_2 = b y_0$

and thus  $y(t) = y_0 e^{-bt} (1 + bt)$

Final solution for this case is

$y(t) = y_0 e^{-bt} (1 + bt)$

for  $b > 0$  and  $y_0 > 0$ .

One trick for finding a solution of  
variable coefficient 2<sup>nd</sup> order linear homogeneous ODE

$$y'' + p(x)y' + q(x)y = 0 \quad (*)$$

Here try  $y = x^m$  is  
a solution to  $(*)$

Then

$$m(m-1)x^{m-2} + pmx^{m-1} + qx^m = 0$$

Already done!

for constant coefficient  
case [Algorithm is:

- find AE and its roots
- Write sol. as per roots

Remember! logic was  
trial solution  $e^{mx}$

$$\Rightarrow [(m(m-1) + mp + q)x^2]x^{m-2} = 0 \quad \begin{array}{l} \text{Never true} \\ \text{if } p \text{ & } q \text{ are constants.} \end{array}$$

$$px + qx^2 = 0 \Leftrightarrow y = cx \text{ is a solution to } (*)$$

$$2 + 2px' + qx^2 = 0 \Leftrightarrow y = x^2 \text{ is a solution to } (*)$$

The above trick can be combined by Thm B

order-reduction  
method

### Example

Solve

$$x^2 y'' - 2x(1+2x) y' + 2(1+2x)y = 0 \quad \text{--- Eq1}$$

$$p(x) = -\frac{2(1+2x)}{x} \quad q(x) = \frac{2(1+2x)}{x^2}$$

Since  $p x + q x^2 = 0$ , thus  $y = x$  is a solution to Eq1.

Then, invoke thm B for second solution

$$y_2 = y_1 \cdot u$$

$$\begin{aligned} \text{when } u &= \int \frac{1}{y_1^2} e^{-\int p(x) dx} dx \\ &= \int \frac{1}{x^2} e^{+\int (\frac{2}{x} + 2) dx} dx \\ &= \int \frac{1}{x^2} e^{(\ln x^2 + 2x)} dx = \int \frac{1}{x^2} e^{\ln x^2} \cdot e^{2x} dx \\ &= \frac{1}{2} e^{2x} \end{aligned}$$

$$\text{Thus } y_2 = \frac{1}{2} x e^{2x}$$

and general solution to Eq1 is

$$y(x) = C_1 x + C_2 \left( \frac{x}{2} e^{2x} \right)$$

SL Ross (3rd edition)

## Cauchy - Euler equation

$$a_0 x^n y^{(n)} + a_1 x^{n-1} y^{(n-1)} + \dots + a_{n-1} x y' + a_n y = F(x)$$

( $a_0, a_1, a_2, \dots, a_n$  are constants)

By using transformation  $x = e^t$  the Cauchy - Euler ODE reduces to a constant coefficient ODE - for details read section 4.5 (pages 164 - 169 of SL Ron).

Otherwise the trick of guessing  $y = x^m$  as a solution works nicely for Cauchy - Euler problem. Read a remark given below the Ques. 9 in tutorial sheet for 2nd order

Example Solve IVP

$$\begin{cases} x^2 y'' - 4x y' + 6y = 0 \\ y(2) = 0 \\ y'(2) = 4 \end{cases}$$

ODE is:  $x^2 y'' - 4x y' + 6y = 0$  — Eq

Take  $y = x^m$ . Then, we obtain

$$x^2 m(m-1)x^{m-2} - 4x m x^{m-1} + 6x^m = 0$$

$$\Rightarrow [m(m-1) - 4m + 6] x^m = 0$$

$$\Rightarrow [m^2 - 5m + 6] x^m = 0$$

so  $x^m$  is a solution to Eq when  $m^2 - 5m + 6 = 0$

$$\Rightarrow (m-3)(m-2) = 0$$

$$\Rightarrow m=2, 3$$

Hence  $y(t) = C_1 x^2 + C_2 x^3$

By putting initial values we obtain

$$\begin{aligned} 4C_1 + 8C_2 &= 0 \\ 4C_1 + 12C_2 &= 4 \end{aligned} \Rightarrow \begin{aligned} C_2 &= 1 \\ C_1 &= -2 \end{aligned}$$

Hence solution to IVP is

$$y(t) = -2x^2 + x^3$$
